Type Theory and Coq 2023-2024 17-11-2023 15:30-17:30

Write your name and student number on each paper that you hand in.

This exam consists of 9 exercises. Each exercise is worth 10 points. The first 10 points are free. The final mark is the number of points divided by 10.

Write all natural deduction proofs and type derivations using the notation from Femke's course notes.

Good luck!

1. Consider the lambda term:

$$\lambda xy. x(y(yx))$$

Apply the PT algorithm to this term, and determine either a principal type for it, or the fact that this term is not typable in simple type theory. Explicitly give all stages of the algorithm.

2. Consider the following type of simple type theory:

$$(a \rightarrow a \rightarrow b) \rightarrow a \rightarrow b$$

Now answer the following two questions:

- (a) Give an inhabitant of this type.
- (b) Give a type derivation that shows that this inhabitant has the appropriate type.
- 3. Consider the following term of λP :

$$\lambda H: (\Pi x: D. \Pi y: D. Rxy). \lambda x: D. Hxx$$

In this term there are free variables

$$D:*$$
 $R:D\to D\to *$

which represent the domain of quantification, and a binary relation on this domain.

Now answer the following three questions:

(a) This term is a proof term of a proof in predicate logic. Give the statement that is proved as a formula of predicate logic.

- (b) Give the natural deduction proof of this statement that corresponds to this term. If you need to check a variable condition, indicate where this is the case, and why it holds.
- (c) Does this proof contain a detour? Explain your answer.

Note that you should not give a type derivation of this term.

4. Give type derivations in λP of the following judgment:

$$a:*, x:a, y:a \vdash x:a$$

For the rules of λP see page 5.

5. An impredicative definition of the natural numbers in $\lambda 2$ is:

$$\mathsf{nat}_2 := \Pi a : *. (a \to a) \to a \to a$$

Each natural number n is encoded as a Church numeral, which takes a type, a function and an argument, and applies that function n times to the argument. So we have that

$$n a f x \rightarrow_{\beta} f^n x$$

For example, the number three is encoded as:

$$\lambda a : *. \lambda f : a \rightarrow a. \lambda x : a. f(f(fx))$$

Note that this term indeed has type nat_2 .

Define a function

$$\mathsf{succ}_2 : \mathsf{nat}_2 \to \mathsf{nat}_2$$

that corresponds to the successor function on these natural numbers.

6. We define an inductive type in Coq of binary trees with natural numbers at the leaves:

```
Inductive nattree : Set :=
| node : nattree -> nattree -> nattree
| leaf : nat -> nattree.
```

The recursor of this type has type:

```
nattree_rec
```

```
: forall P : nattree -> Set,
  (forall t1 : nattree, P t1 ->
    forall t2 : nattree, P t2 ->
        P (node t1 t2)) ->
  (forall n : nat, P (leaf n)) ->
  forall t : nattree, P t
```

Now answer the following two questions:

(a) Define a function nattree_sum that adds all the natural numbers at the leaves of a tree, using Fixpoint and match. This function should have type:

nattree_sum

: nattree -> nat

In your definition you can use the addition function on natural numbers:

plus

: nat -> nat -> nat

- (b) Define the function nattree_sum_rec that computes the same sum, by applying nattree_rec to appropriate arguments.
- 7. We define an inductive type in Coq of polymorphic binary trees:

Inductive polytree (A : Set) : Set :=

| polynode : polytree A -> polytree A -> polytree A

| polyleaf : A -> polytree A.

Give the type of the (dependent) induction principle polytree_ind for this type.

8. Consider the untyped lambda term:

$$M_8 := II(III)$$

In this we have as always that $I := (\lambda x. x)$.

Now answer the following two questions:

- (a) Give the reduction graph of this term. If there are multiple ways to reduce a term to some other term, indicate this with multiple arrows.
- (b) Compute M_8^* and $(M_8^*)^*$. Just giving the answers is enough, you do not need to explain how you obtained them.

The definition of M^* is:

$$x^* = x$$

$$(\lambda x. M)^* = \lambda x. M^*$$

$$(MN)^* = \begin{cases} P^*[x := N^*] & \text{if } M = \lambda x. P \\ M^*N^* & \text{otherwise} \end{cases}$$

9. Consider the lambda term:

$$\lambda x. (\lambda f. x) ((\lambda g. g) ((\lambda yz. y) x))$$

This term is typable in simple type theory. A typed version is:

$$\lambda x: a. (\lambda f: b \to a. x) ((\lambda g: b \to a. g) ((\lambda y: a. \lambda z: b. y) x))$$

or in Coq notation:

Now answer the following three questions:

- (a) Indicate what the redexes in this term are. You can do this either in the untyped or in the typed version of the term.
- (b) For each of these redexes give its height.
- (c) Indicate which redex or redexes may be contracted according to the reduction strategy from Turing's proof of weak normalization for simple type theory.

The height of a redex $(\lambda x : A.M) N$ is the height of the type of $(\lambda x : A.M)$. The height function h is defined on types by:

$$h(a) = 0$$
 for atomic types a
 $h(A \to B) = \max(h(A) + 1, h(B))$

which implies that:

$$h(A_1 \to \cdots \to A_n \to a) = \max(h(A_1), \dots, h(A_n)) + 1$$

Typing rules of λP

axiom
