

Programming with Higher Inductive Types

Henning Basold, Herman Geuvers, Niels van der Weide

December 20, 2016

How to define Integers

```
data Pos =  
  One : Pos  
  | S : Pos → Pos  
data ℤ =  
  Minus : Pos → ℤ  
  | Zero : ℤ  
  | Plus : Pos → ℤ
```

How to define Integers

A more logical definition of \mathbb{Z} would be

```
data  $\mathbb{Z}$  =  
  z :  $\mathbb{Z}$   
| s :  $\mathbb{Z} \rightarrow \mathbb{Z}$   
| p :  $\mathbb{Z} \rightarrow \mathbb{Z}$ 
```

and we require that S and P are inverses.

How to define Integers

A more logical definition of \mathbb{Z} would be

```
data  $\mathbb{Z}$  =  
  z :  $\mathbb{Z}$   
| s :  $\mathbb{Z} \rightarrow \mathbb{Z}$   
| p :  $\mathbb{Z} \rightarrow \mathbb{Z}$ 
```

and we require that S and P are inverses.

However, inductive types should be 'freely generated'. We can't allow extra equations.

Our Goal: Higher Inductive Types

Higher inductive types allow the programmer to define data types with extra equations.

Topics

- ▶ What's 'equality'?
- ▶ What are Higher Inductive Types (HITs), and what can we do with them?
- ▶ In the end: how can we implement this in Coq? (Coq doesn't have HITs)

Equality by rewriting (**Definitional Equality**)

Functional languages rewrite terms.

```
data nat =  
  Z : nat  
  | S : nat → nat
```

```
plus : nat → nat → nat  
plus Z m = m  
plus (S n) m = S (plus n m)
```

We rewrite 'plus (S Z) (S Z)' to 'S (S Z)'.

Equality as a proposition (**Propositional Equality**)

Using Curry-Howard we can define equality as a type.

```
data Eq (A : Type) : A → A → Type =  
  refl : (a : A) → Eq A a a
```

We denote the type 'Eq A a b' by ' $a = b$ '.

Note: we can also talk about *equalities between equalities* via the type 'Eq (Eq A a b) p q'. These are called **higher equalities**.

Comparison

Definitional equality is stronger, but propositional is more flexible.
We will *mostly* use **propositional** equality.

Examples of Higher Inductive Types

```
data N/2N =  
  z : N/2N  
| s : N/2N → N/2N  
| mod : z = s(s z)
```

Examples of Higher Inductive Types

```
data  $\mathbb{N}/2\mathbb{N}$  =  
  z :  $\mathbb{N}/2\mathbb{N}$   
| s :  $\mathbb{N}/2\mathbb{N} \rightarrow \mathbb{N}/2\mathbb{N}$   
| mod :  $z = s(s\ z)$ 
```

Note: if we have $f : A \rightarrow B$ and $p : x = y$ (with $x, y : A$), then we have $\text{ap}(f, p) : f\ x = f\ y$.

Examples of Higher Inductive Types

```
data  $\mathbb{N}/2\mathbb{N}$  =  
  z :  $\mathbb{N}/2\mathbb{N}$   
  | s :  $\mathbb{N}/2\mathbb{N} \rightarrow \mathbb{N}/2\mathbb{N}$   
  | mod :  $z = s(s\ z)$ 
```

Note: if we have $f : A \rightarrow B$ and $p : x = y$ (with $x, y : A$), then we have $\text{ap}(f, p) : f\ x = f\ y$. This gives

$$\text{ap}(S, \text{mod}) : S\ z = S(S\ z),$$

$$\text{ap}(S, \text{ap}(S, \text{mod})) : S(S\ z) = S(S(S\ z)),$$

and so on.

Examples of Higher Inductive Types

```
data  $\mathbb{Z}$  =  
  Z :  $\mathbb{Z}$   
| S :  $\mathbb{Z} \rightarrow \mathbb{Z}$   
| P :  $\mathbb{Z} \rightarrow \mathbb{Z}$   
| inv1 : (x :  $\mathbb{Z}$ )  $\rightarrow$  P(S x) = x  
| inv2 : (x :  $\mathbb{Z}$ )  $\rightarrow$  S(P x) = x
```

What about higher equalities?

We have $P : \mathbb{Z} \rightarrow \mathbb{Z}$ and

$$\text{inv } 2(S(PZ)) : S(PZ) = S(P(S(PZ))),$$

What about higher equalities?

We have $P : \mathbb{Z} \rightarrow \mathbb{Z}$ and

$$\text{inv } 2(S(PZ)) : S(PZ) = S(P(S(PZ))),$$

so we get

$$\text{ap}(P, \text{inv } 2(S(PZ))) : P(S(PZ)) = P(S(P(S(PZ))))$$

What about higher equalities?

We have $P : \mathbb{Z} \rightarrow \mathbb{Z}$ and

$$\text{inv } 2(S(PZ)) : S(PZ) = S(P(S(PZ))),$$

so we get

$$\text{ap}(P, \text{inv } 2(S(PZ))) : P(S(PZ)) = P(S(P(S(PZ))))$$

We also have

$$\text{inv } 1(P(S(PZ))) : P(S(PZ)) = P(S(P(S(PZ)))).$$

Are these equal?

Short Intermezzo: Hedberg's Theorem

Theorem

If we give an inhabitant of $A + (A \rightarrow \perp)$ for a type A , then all inhabitants of $x = y$ for $x, y : A$ are equal.

Short Intermezzo: Hedberg's Theorem

Theorem

If we give an inhabitant of $A + (A \rightarrow \perp)$ for a type A , then all inhabitants of $x = y$ for $x, y : A$ are equal.

Briefly, if A has decidable equality, then all proofs of equality in A are equal.

Short Intermezzo: Hedberg's Theorem

Theorem

If we give an inhabitant of $A + (A \rightarrow \perp)$ for a type A , then all inhabitants of $x = y$ for $x, y : A$ are equal.

Briefly, if A has decidable equality, then all proofs of equality in A are equal.

Equivalently, if two equalities in a type are unequal, then that type does not have decidable equality.

How to Program with HITs?

How to map $\mathbb{N}/2\mathbb{N}$ to some type A ? What about \mathbb{Z} ?

Programming with $\mathbb{N}/2\mathbb{N}$

To make $\mathbb{N}/2\mathbb{N} \rightarrow A$, we need to give

- ▶ $z : A$ which is the image of Z ;
- ▶ $s : A \rightarrow A$ which is the image of S ;

Programming with $\mathbb{N}/2\mathbb{N}$

To make $\mathbb{N}/2\mathbb{N} \rightarrow A$, we need to give

- ▶ $z : A$ which is the image of Z ;
- ▶ $s : A \rightarrow A$ which is the image of S ;
- ▶ an equality (a proof obligation)

$$m : z = s(s z).$$

Programming with $\mathbb{N}/2\mathbb{N}$

Seeing $\mathbb{N}/2\mathbb{N}$ as booleans, we can negate it.

- ▶ Choose $A = \mathbb{N}/2\mathbb{N}$;
- ▶ For z we pick $S Z$;
- ▶ For s we pick S ;
- ▶ The proof obligation is: $S Z = S(S(S Z))$. We give

$\text{ap}(S, \text{mod})$

Programming with \mathbb{Z}

To make $\mathbb{Z} \rightarrow A$, we need to give

- ▶ $z : A$ which is the image of Z ;
- ▶ $s : A \rightarrow A$ and $p : A \rightarrow A$ for S and P respectively;

Programming with \mathbb{Z}

To make $\mathbb{Z} \rightarrow A$, we need to give

- ▶ $z : A$ which is the image of Z ;
- ▶ $s : A \rightarrow A$ and $p : A \rightarrow A$ for S and P respectively;
- ▶ equalities (proof obligations)

$$i_1 : (a : A) \rightarrow a = p(s\ a),$$

$$i_2 : (a : A) \rightarrow a = s(p\ a).$$

\mathbb{Z} does not have decidable equality!

In Homotopy Type Theory \mathbb{Z} does not have decidable equality.
For the proof we assume we have

- ▶ A type C ;
- ▶ A point $b : C$;
- ▶ An equality $l : b = b$ such that there is no equality between l and $\text{refl } b$.

(We can prove that there is such a type assuming Voevodsky's Univalence Axiom)

The proof

We make $f : \mathbb{Z} \rightarrow C$.

- ▶ We send Z to b .
- ▶ We send S and P to the identity map;
- ▶ For inv1 we need to prove $b = b$ for which we take I ;
- ▶ For inv2 we also need to prove $b = b$ which we prove by $\text{refl } b$.

The proof

We make $f : \mathbb{Z} \rightarrow C$.

- ▶ We send Z to b .
- ▶ We send S and P to the identity map;
- ▶ For inv1 we need to prove $b = b$ for which we take l ;
- ▶ For inv2 we also need to prove $b = b$ which we prove by $\text{refl } b$.

Now we have

$$\text{ap}(f, \text{ap}(P, \text{inv } 2(S(PZ)))) = \text{refl } b,$$

$$\text{ap}(f, \text{inv } 1(P(S(PZ)))) = l.$$

So, these paths are unequal, and thus \mathbb{Z} does not have decidable equality.

How to do this in Coq?

Coq does not have HITs, but you can add axioms.

```
Module Export Ints.
```

```
Private Inductive Z : Type :=
```

```
| nul : Z  
| succ : Z → Z  
| pred : Z → Z.
```

```
Axiom inv1 : forall n : Z, n = pred(succ n).
```

```
Axiom inv2 : forall n : Z, n = succ(pred n).
```

How to do this in Coq?

The recursion principle is more complicated.

Fixpoint Z_rec

(P : Type)

(a : P)

(s : P → P)

(p : P → P)

(i1 : forall (m : P), m = p(s m))

(i2 : forall (m : P), m = s(p m))

(x : Z)

{struct x}

: P

:=

(match x return _ → _ → P with

| nul ⇒ fun _ ⇒ fun _ ⇒ a

| succ n ⇒ fun _ ⇒ fun _ ⇒ s ((Z_rec P a s p i1 i2) n)

| pred n ⇒ fun _ ⇒ fun _ ⇒ p ((Z_rec P a s p i1 i2) n)

end) i1 i2.

How to do this in Coq?

Computation rules for the equalities go as expected.

```
Axiom Z_rec_beta_inv1 :
```

```
forall
```

```
  (P : Type)
```

```
  (a : P)
```

```
  (s : P → P)
```

```
  (p : P → P)
```

```
  (i1 : forall (m : P), m = p(s m))
```

```
  (i2 : forall (m : P), m = s(p m))
```

```
  (n : Z)
```

```
, ap (Z_rec P a s p i1 i2) (inv1 n) = i1 (Z_rec P a s p i1 i2 n).
```

```
end Ints.
```
